Draft Not To Be Quoted 2

### 48 1 Overview

- 49 This chapter covers emissions from waste water handling. In most cases, this will be an
- 50 insignificant source for air pollutants. However, in urban areas, non-methane volatile organic
- 51 compounds (NMVOC) emissions from waste water treatment plants will be of local importance.
- 52 Activities considered within this sector are biological treatment plants and latrines (storage tanks
- of human excreta, located under naturally ventilated wooden shelters).
- 54 Biological treatment plants are only of minor importance for emissions into air, and the most
- important of these emissions are greenhouse gases (CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub>O). Air pollutants include
- 56 NMVOC and NH<sub>3</sub>; however the contribution to the total emissions is only minor and only of local
- 57 importance.
- Latrines are generally only a minor source of emissions (mainly NH<sub>3</sub>); however, in Poland, the
- contribution of this activity to the total ammonia emissions is reported to be about 3 %.

60

61

# 2 Description of sources

### 62 2.1 Process description

This section describes the processes and emissions from biological treatment plants and latrines.

### 64 2.1.1 Biological treatment plants

- The main type of wastewater treatment plants in the Netherlands are low-load biological treatment
- plants with aeration by point aerators. For dephosphatizing, the simultaneous process is mostly
- 67 used. Denitrification generally occurs using anaerobic zones in the wastewater treatment basin.

#### 68 **2.1.2** *Latrines*

- 69 A latrine is a simple 'dry' toilet built outside the house, usually in a backyard. A storage tank
- 70 under the latrine can be a hole dug in the ground, or a concrete reservoir. Capacity of the tank can
- vary between 1 m<sup>3</sup> and 2 m<sup>3</sup>, depending on the family size. The time of storage can vary between
- a few months and 'forever'. Tanks are emptied by cesspool emptiers or contents are deposited on
- 73 an animal manure heap. From time to time chlorinated lime is used for latrines disinfection.
- Nitrogen content in human excreta depends on the diet, health and physical activity of an
- individual. A moderately active person with a daily intake of about 300 g of carbohydrates, 100 g
- of fat and 100 g of proteins excretes about 16 g of nitrogen. Kidneys void 95 % of nitrogen and
- 77 the residual 5 % is excreted mostly as N in faeces. A person on European diet voids 80 to 90 % of
- 78 nitrogen as urea (Harper et al, 1983).
- 79 Ammonia emissions derive mainly from the decomposition of urea and uric acid. Excreted urea is
- 80 hydrolysed to NH<sub>3</sub> through the action of microbial urea. The rate of this hydrolysis depends on
- 81 temperature, pH, amount of urea present and water content. The hydrolysis increases pH of
- 82 collected urine and faeces to about 9. The decomposition of protein in faeces is a slow process, but
- during storage, 40 to 70 % of total N is converted to the NH<sub>4</sub><sup>+</sup> form (European Centre for
- 84 Ecotoxicology and Toxicology of Chemicals (ECETOC), 1994).

86

88

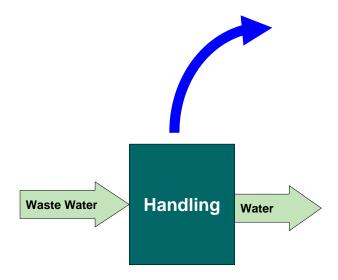

#### Table 2-1 Daily excretion of nitrogen in normal urine (pH 6.0) (source: Harper et al., 1983)

Compound	Quantity [g]	N equivalent [g]
Nitrogen compounds (total)	25–35	10–14
Urea (50 % of solid compounds depends on diet)	25–30	10–12
Creatinine	1.4 (1-1.8)	0.5
Ammonia	0.7 (0.3–1)	0.4
Uric acid	0.7 (0.5–0.8)	0.2
N in other compounds (e.g. amino acids)		0.5

Nitrogen is emitted from latrines as NH<sub>3</sub> in a free evaporation process. Ammonia emission from

latrines depends on quantity and form of nitrogen compounds in human excreta, as well as on

weather conditions.

90 91

Figure 2-1 Process scheme for source category 5.D Waste water handling

92

93

96

### 2.2 Techniques

An overview is given in the process description. There are no specific techniques that are applicable here.

### 2.3 Emissions

- 97 In general, air emissions of persistent organic pollutants (POPs) as well as NMVOC, CO and NH<sub>3</sub>
- 98 occur from waste water treatment plants, but are mostly insignificant for national total emissions.
- 99 However, NMVOC emissions from waste water treatment plants to air may in some cases be
- significant in urban areas and may even contribute significantly at a national level. More
- information about these is provided in Sree et al. (2000), Oskouie et al. (2008), Atasoy et al.
- 102 (2004) and Escalasa et al. (2003).

- Emissions from biological treatment plants are mainly greenhouse gases: carbon dioxide, methane
- and nitrous oxide. These emissions are not treated in this chapter; guidance on reporting
- greenhouse gas emissions is provided by the Intergovernmental Panel on Climate Change (IPCC)
- Guidelines. Small quantities of NH<sub>3</sub> and NMVOC are emitted as well.
- Emissions from latrines are mainly NH<sub>3</sub> and also small quantities of CH<sub>4</sub>.

#### 2.4 Controls

- Reduction of ammonia emissions from latrines is possible by the installation of water supply and
- sewage systems, which is particularly possible in towns.

111

112

108

### 3 Methods

- This source is expected to be only of minor importance for emissions of air pollutants and little
- information is available on estimating emissions from waste water handling.

### 115 3.1 Choice of method

- Figure 3-1 presents the procedure to select the methods for estimating emissions from waste water
- handling. The basic ideas behind this procedure are:
- if detailed information is available, use it;
- if the source category is a key category, a Tier 2 or better method must be applied and detailed
- input data must be collected. The decision tree directs the user in such cases to the Tier 2
- method, since it is expected that it is more easy to obtain the necessary input data for this
- approach than to collect facility-level data needed for a Tier 3 estimate;
- the alternative of applying a Tier 3 method, using detailed process modelling, is not explicitly
- included in this decision tree. However, detailed modelling will always be done at facility
- level and results of such modelling could be seen as 'facility data' in the decision tree.

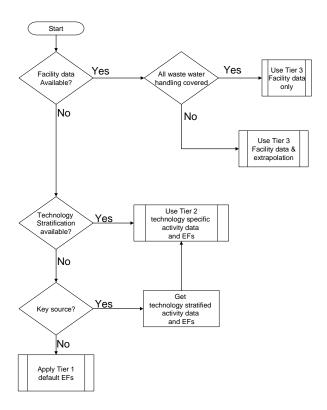

Figure 3-1 Decision tree for source category 5.D Waste water handling

128

129

131

136

### 3.2 Tier 1 default approach

#### 130 **3.2.1** Algorithm

The Tier 1 approach for emissions from waste water handling uses the general equation:

$$E_{pollutant} = AR_{production} \times EF_{pollutant}$$
 (1)

- This equation is applied at the national level. The Tier 1 emission factors assume an averaged or
- typical technology and abatement implementation in the country and integrate all different sub-
- processes in the handling of waste water.

#### 3.2.2 Default emission factors

- 137 A default emission factor for NMVOC emissions from waste water handling has been derived
- from a Turkish study (Atasoy et al., 2004). This emission factor should be handled with care, since
- it may not be applicable to all waste water treatment plants. Furthermore, the emission factors
- reported in literature show a high variation. More specific information is available in the
- references indicated in subsection 2.3 of the present chapter. Emission factors for all other
- pollutants are not available and may be assumed negligible in most cases; therefore, this chapter
- does not report emission factors for these other pollutants.

- For guidance on emissions from CH<sub>4</sub> and N<sub>2</sub>O emissions from this source, refer to the IPCC
- Guidelines for National Greenhouse Gas Inventories (IPCC, 2006).

Table 3-1 Tier 1 emission factors for source category 5.D Wastewater handling

Tier 1 default emission factors					
	Code	Name			
NFR Source Category	5.D	Wastewater handling			
Fuel	NA				
Not applicable	NOx, CO, SOx, Aldrin, Chlordane, Chlordecone, Dieldrin, Endrin, Heptachlor, Heptabromo-biphenyl, Mirex, Toxaphene, HCH, DDT, PCB, PCDD/F, Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Indeno(1,2,3-cd)pyrene, Total 4 PAHs, HCB, PCP, SCCP				
Not estimated	NH3, TSP, PM10, PM2.5, BC, Pb, Cd, Hg, As, Cr, Cu, Ni, Se, Zn				
Pollutant	Value	Unit	95% confidence interval		Reference
			Lower	Upper	
NMVOC	15	mg/m3 waste water handled	5	50	Atasoy et al. (2004)

#### 147 **3.2.3** Activity data

The relevant activity statistic for the Tier 1 approach is the total amount of waste water handled by all waste water treatment plants in the country.

#### 150

151

146

### 3.3 Tier 2 technology-specific approach

#### 152 **3.3.1 Algorithm**

- 153 The Tier 2 approach is similar to the Tier 1 approach. To apply the Tier 2 approach, both the
- activity data and the emission factors need to be stratified according to the different
- techniques/processes that may occur in the country.
- The approach followed to apply a Tier 2 approach is as follows:
- 157 Stratify the waste water handling in the country to model the different product and process types
- occurring in the national waste water handling 'industry' into the inventory by:
- defining the handling using each of the separate product and/or process types (together called 'technologies' in the formulae below) separately; and
- applying technology specific emission factors for each of these 'technologies':

$$E_{pollutant} = \sum_{technologies} AR_{handling technology} \times EF_{technology pollutant}$$
 (2)

where:

164 AR<sub>handling,technology</sub> = the waste water handling rate within the source category, using this specific 'technology',

- $EF_{technology,pollutant}$  = the emission factor for this technology and this pollutant.
- A country where only one technology is implemented will result in a penetration factor of 100 %
- and the algorithm reduces to:

$$E_{pollutant} = AR_{production} \times EF_{technologypollutant}$$
 (3)

- 170 where:
- $E_{pollutant}$  = the emission of the specified pollutant,
- $AR_{production}$  = the activity rate for the waste incineration,
- $EF_{pollutant}$  = the emission factor for this pollutant.
- The emission factors in this approach still will include all sub-processes within the waste
- incineration.

### 3.3.2 Technology-specific emission factors

- 177 This section presents emissions from waste water handling (the emission factor is identical to the
- emission factor used in the Tier 1 approach), but also considers separately NH<sub>3</sub> emissions from
- 179 latrines.

176

185

#### 180 **3.3.2.1** Latrines

- The emission factor for latrines has been determined from the similarity between latrines and open
- storage of animal manure in lagoons or ponds (Guidebook, 2006). Emission factors for CO<sub>2</sub>, N<sub>2</sub>O
- and CH<sub>4</sub> are not provided in this chapter. Information about these greenhouse gas emissions can
- be found in the 2006 IPCC Guidelines (IPCC, 2006).

#### 3.3.2.2 Waste water handling

- 187 The default Tier 2 emission factor for NMVOC emissions from waste water handling is given in
- 188 Table 3-3 below. The emission factor is equivalent to the emission factor used in the Tier 1 default
- approach.

186

#### 191 **3.3.3 Abatement**

192 Reduction efficiencies when abatement is in place are not available for this source category.

#### 3.3.4 Activity data

- 194 It is assumed that tenants of urban flats and country houses with no water-flushed toilet have to
- use latrines outside the house. As it follows from Polish statistical data of 1992, 30 % of country
- houses and 4 % of urban flats had no water supply system, and 48 % of country houses and 14 %
- of urban flats had no water-flushed toilets. The number of people in an average family in town or
- countryside living together in the same home is needed for estimation of total number of latrine
- users. Based on that, it was estimated that about 10 million Polish inhabitants (approximately
- 200 25 % of the population) did not use water-flushed toilets. Changes of that total number during
- summer holidays are not accounted for.
- For waste water handling, the relevant activity data is the total amount of waste water handled.

### 3.4 Tier 3 emission modelling and use of facility data

Not available for this source.

203

193

### 206 4 Data quality

### 207 4.1 Completeness

- No specific issues.
- **4.2 Avoiding double counting with other sectors**
- 210 No specific issues.

### 211 4.3 Verification

- 212 4.3.1 Best Available Technique emission factors
- 213 BAT emission factors are not available for this source. However, there is an extensive amount of
- 214 information with regard to waste water treatment available in the Reference Document on Best
- 215 Available Techniques in Common Waste Water and Waste Gas Treatment / Management Systems
- 216 (European Commission, 2003).

### 217 4.4 Developing a consistent time series and recalculation

- 218 No specific issues.
- 219 4.5 Uncertainty assessment
- No specific issues.
- 221 4.5.1 Emission factor uncertainties
- No specific issues.
- 223 4.5.2 Activity data uncertainties
- No specific issues.

### 225 4.6 Inventory quality assurance/quality control QA/QC

- No specific issues.
- 227 4.7 Gridding
- 228 For latrines, it is good practice to disaggregate national totals on the basis of population, taking
- 229 urban and rural differences in the number of latrines into account.

# 230 4.8 Reporting and documentation

No specific issues.
